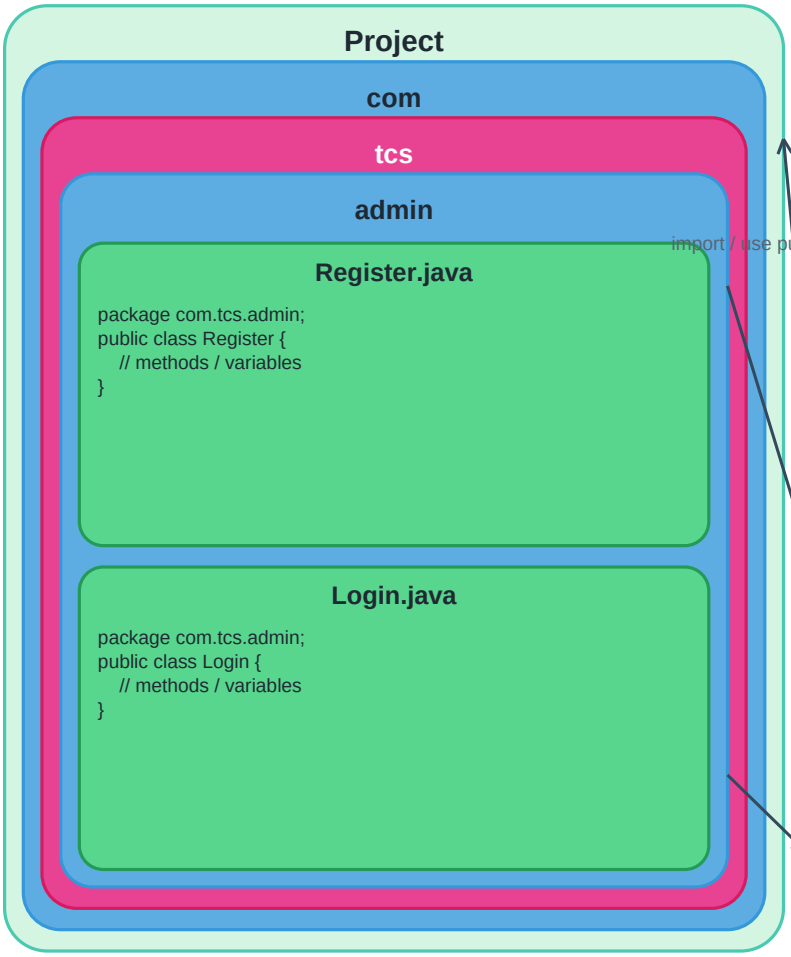
Corrected version of your Java package diagram

Same concept and flow as your handwritten diagram, with the missing/correct points added.



Main.java

```
import com.tcs.admin.Register;
import com.tcs.admin.Login;
public class Main {
    public static void main(String[] args) {
        // calls methods here
    }
}
```

Access modifiers

default / package-private
→ same package only

protected
→ same package + subclasses in other packages

public
→ accessible from other packages too

private
→ declaring class only

What does import do?

- Lets Main refer to a class by its simple name.
- It does NOT bypass private/default/protected access.
- The class/member must still be accessible.

Application flow

Start application → main() runs
→ Main can call accessible methods of Register/Login.

Important corrections from the handwritten notes

1. If Main.java is in com.tcs.admin, Register/Login do not need import statements.
2. If Main.java is in another package, use the two imports shown above and make Register/Login public.
3. A public class can be used from another package, but its members must also have suitable access.
